Non-linear hypotheses

When number of features is large, it's difficult to calculate parameters in a short time.

Neuronal and the brain

Model and representation 1

$$z = \sum_{i=0} w_i x_i$$

$$g(z) = \frac{1}{1+e^{-z}}$$

$$\text{即 } h_{\Theta}(x) = \frac{1}{1+e^{-\Theta^T x}}$$

$$a_i^{(j)} = g\left(\sum_{k=0} \Theta_{ik}^{(j-1)} x_k\right)$$

$$a^{(j)} = g(\Theta^{j-1} x)$$

$$\Theta^{j-1} \text{ is } s_j * (s_{j-1} + 1)$$

Model and representation 2

$$z^{(2)} = \Theta^{(1)} * a^{(1)}$$

$$a^{(2)} = g(z^{(2)})$$

$$\text{Add } a_0^{(2)} = 1.$$

$$z^{(3)} = \Theta^{(2)} * a^{(2)}$$

$$h_{\Theta}(x) = a^{(3)} = g(z^{(3)})$$

Examples and intuitions 1

$$y = x_1 \text{ XOR } x_2$$

$$y = x_1 \text{ XNOR } x_2$$

$$y = \text{NOT}(x_1 \text{ XOR } x_2)$$

Examples and intuitions 2

$$y = x_1 \text{ AND } x_2$$

$$y = x_1 \text{ OR } x_2$$

Multi-class classification

$$h_{\Theta}(x) \in \mathbb{R}^n$$

Training set: $(x^{(i)}, y^{(i)})$

$$y_j^{(i)} = 1, y_{k \neq j}^{(i)} = 0$$
